(54) Title: AMIDE COMPOUNDS FOR INHIBITING PROTEIN KINASES

(57) Abstract: Amide compounds that modulate and/or inhibit the activity of certain protein kinases are described. These com-  
pounds and pharmaceutical compositions containing them are capable of mediating tyrosine kinase signal transduction in order to  
modulate and/or inhibit unwanted cell proliferation. The invention is also directed to the therapeutic or prophylactic use of pharma-  
ceutical compositions containing such compounds, and to methods of treating cancer as well as other disease states associated with  
unwanted angiogenesis and/or cellular proliferation, such as diabetic retinopathy, neovascular glaucoma, rheumatoid arthritis, and  
psoriasis, by administering effective amounts of such compounds.

# AMIDE COMPOUNDS

## FOR INHIBITING PROTEIN KINASES

5           This applications claims the benefit of U.S. Provisional Application Serial No. 60/177,059, filed January 21, 2000, the contents of which are hereby incorporated by reference herein.

### FIELD OF THE INVENTION

10           This invention is directed to amide compounds that mediate and/or inhibit the activity of certain protein kinases, and to pharmaceutical compositions containing such compounds. The invention is also directed to the therapeutic or prophylactic use of such compounds and compositions, and to methods of treating cancer as well as other disease states associated with unwanted angiogenesis and/or cellular proliferation, by administering effective amounts of such compounds.

### BACKGROUND OF THE INVENTION

15           Protein kinases are a family of enzymes that catalyze phosphorylation of the hydroxyl group of specific tyrosine, serine, or threonine residues in proteins. Typically, such phosphorylation dramatically perturbs the function of the protein, and thus protein kinases are pivotal in the regulation of a wide variety of cellular processes, including metabolism, cell proliferation, cell differentiation, and cell survival. Of the many different cellular functions in which the activity of protein kinases is known to be required, some processes represent attractive targets for therapeutic intervention for certain disease states. Two examples are angiogenesis and cell-cycle control, in which protein kinases play a pivotal role; these processes are essential for the growth of solid tumors as well as for other diseases.

25           Angiogenesis is the mechanism by which new capillaries are formed from existing vessels. When required, the vascular system has the potential to generate new capillary networks in order to maintain the proper functioning of tissues and organs. In the adult, however, angiogenesis is fairly limited, occurring only in the process of wound healing and neovascularization of the endometrium during menstruation. See Merenmies, J., Parada, L. F., Henkemeyer, M., *Cell Growth & Differentiation*, 8, 3-10 (1997). On the other hand, unwanted angiogenesis is a hallmark of several diseases,

such as retinopathies, psoriasis, rheumatoid arthritis, age-related macular degeneration, and cancer (solid tumors). Folkman, *Nature Med.*, 1, 27-31 (1995). Protein kinases which have been shown to be involved in the angiogenic process include three members of the growth factor receptor tyrosine kinase family: VEGF-R2 (vascular endothelial growth factor receptor 2, also known as KDR (kinase insert domain receptor) and as FLK-1); FGF-R (fibroblast growth factor receptor); and TEK (also known as Tie-2).

VEGF-R2, which is selectively expressed on endothelial cells, binds the potent angiogenic growth factor VEGF and mediates the subsequent signal transduction through activation of its intracellular kinase activity. Thus, it is expected that direct inhibition of the kinase activity of VEGF-R2 will result in the reduction of angiogenesis even in the presence of exogenous VEGF (see Strawn et al., *Cancer Research*, 56, 3540-3545 (1996)), as has been shown with mutants of VEGF-R2 which fail to mediate signal transduction. Millauer et al., *Cancer Research*, 56, 1615-1620 (1996). Furthermore, VEGF-R2 appears to have no function in the adult beyond that of mediating the angiogenic activity of VEGF. Therefore, a selective inhibitor of the kinase activity of VEGF-R2 would be expected to exhibit little toxicity.

Similarly, FGF-R binds the angiogenic growth factors aFGF and bFGF and mediates subsequent intracellular signal transduction. Recently, it has been suggested that growth factors such as bFGF may play a critical role in inducing angiogenesis in solid tumors that have reached a certain size. Yoshiji et al., *Cancer Research*, 57, 3924-3928 (1997). Unlike VEGF-R2, however, FGF-R is expressed in a number of different cell types throughout the body and may or may not play important roles in other normal physiological processes in the adult. Nonetheless, systemic administration of a small molecule inhibitor of the kinase activity of FGF-R has been reported to block bFGF-induced angiogenesis in mice without apparent toxicity. Mohammad et al., *EMBO Journal*, 17, 5996-5904 (1998).

TEK (also known as Tie-2) is another receptor tyrosine kinase selectively expressed on endothelial cells which has been shown to play a role in angiogenesis. The binding of the factor angiopoietin-1 results in autophosphorylation of the kinase domain of TEK and results in a signal transduction process which appears to mediate

the interaction of endothelial cells with peri-endothelial support cells, thereby facilitating the maturation of newly formed blood vessels. The factor angiopoietin-2, on the other hand, appears to antagonize the action of angiopoietin-1 on TEK and disrupts angiogenesis. Maisonpierre et al., *Science*, 277, 55-60 (1997).

5           As a result of the above-described developments, it has been proposed to treat angiogenesis by the use of compounds inhibiting the kinase activity of VEGF-R2, FGF-R, and/or TEK. For example, WIPO International Publication No. WO 97/34876 discloses certain cinnoline derivatives that are inhibitors of VEGF-R2, which may be used for the treatment of disease states associated with abnormal angiogenesis and/or  
10   increased vascular permeability such as cancer, diabetes, psoriasis, rheumatoid arthritis, Kaposi's sarcoma, haemangioma, acute and chronic nephropathies, atheroma, arterial restinosis, autoimmune diseases, acute inflammation and ocular diseases with retinal vessel proliferation. Two documents described hereinafter disclose certain amide derivatives but do not disclose or teach that any of the compounds may be used  
15   for modulating or inhibiting the activity of protein kinases: WIPO International Publication No. WO 97/03967; and WIPO International Publication No. WO 96/23783.

          In addition to its role in angiogenesis, protein kinases also play a crucial role in cell-cycle control. Uncontrolled cell proliferation is the insignia of cancer. Cell  
20   proliferation in response to various stimuli is manifested by a de-regulation of the cell division cycle, the process by which cells multiply and divide. Tumor cells typically have damage to the genes that directly or indirectly regulate progression through the cell division cycle.

          Cyclin-dependent kinases (CDKs) are serine-threonine protein kinases that play  
25   critical roles in regulating the transitions between different phases of the cell-cycle, such as the progression from a quiescent stage in G<sub>1</sub> (the gap between mitosis and the onset of DNA replication for a new round of cell division) to S (the period of active DNA synthesis), or the progression from G<sub>2</sub> to M phase, in which active mitosis and cell-division occurs. See, e.g., the articles compiled in *Science*, 274, 1643-1677  
30   (1996). CDK complexes are formed through association of a regulatory cyclin subunit (e.g., cyclin A, B1, B2, D1, D2, D3, and E) and a catalytic kinase subunit (e.g., cdc2

(CDK1), CDK2, CDK4, CDK5, and CDK6). As the name implies, the CDKs display an absolute dependence on the cyclin subunit in order to phosphorylate their target substrates, and different kinase/cyclin pairs function to regulate progression through specific phases of the cell-cycle.

5           It is CDK4 complexed to the D cyclins that plays a critical part in initiating the cell-division cycle from a resting or quiescent stage to one in which cells become committed to cell division. This progression is subject to a variety of growth regulatory mechanisms, both negative and positive. Aberrations in this control system, particularly those that affect the function of CDK4, have been implicated in the  
10 advancement of cells to the highly proliferative state characteristic of malignancies, particularly familial melanomas, esophageal carcinomas, and pancreatic cancers. See, e.g., Hall et al., *Adv. Cancer Res.*, 68, 67-108 (1996); Kamb, *Trends in Genetics*, 11, 136-140 (1995); Kamb et al., *Science*, 264, 436-440 (1994).

A large number of small molecule ATP-site antagonists have been  
15 identified as CDK inhibitors. (See, Webster, *Exp. Opin. Invest. Drugs*, 7, 865-887 (1998), Stover, Et al., *Curr. Opin. Drug Disc. Dev.*, 2, 274-285(1999), Gray et al., *Curr. Med. Chem.*, 6, 859-875 (1999), Sielecki, et al., *J. Med. Chem.*, 43, 1-18 (2000), Crews, et al., *Curr. Opin. Chem. Biol.*, 4, 47-53 (2000), Buolamwini, *Curr. Pharm. Des.*, 6, 379-392 (2000), and Rosania, et al., *Exp. Opin. Ther. Pat.*,  
20 10, 215-230 (2000)). Moreover, the use of compounds as anti-proliferative therapeutic agents that inhibit CDKs is the subject of several patents and publications. For example, U.S. Patent No. 5,621,082 to Xiong et al., discloses nucleic acid encoding an inhibitor of CDK6 and European Patent Publication No. 0 666 270 A2 describes peptides and peptide mimetics that act as inhibitors of CDK1  
25 and CDK2. WIPO International Publication No. WO 97/16447 discloses certain analogs of chromones that are inhibitors of cyclin-dependent kinases, in particular of CDK/cyclin complexes such as CDK4/cyclin D1, which may be used for inhibiting excessive or abnormal cell proliferation, and therefore for treating cancer. WIPO International Publication No. WO 99/21845 describes 4-  
30 aminothiazole derivatives that are useful as CDK inhibitors.

There is still a need, however, for small-molecule compounds that may be readily synthesized and are effective in inhibiting one or more CDKs or CDK/cyclin complexes. Because CDK4 may serve as a general activator of cell division in most cells, and complexes of CDK4 and D-type cyclins govern the early G<sub>1</sub> phase of the cell-cycle, there is a need for effective inhibitors of CDK4, and D-type cyclin complexes thereof, for treating one or more types of tumors. Also, the pivotal roles of cyclin E/CDK2 and cyclin B/CDK1 kinases in the G<sub>1</sub>/S phase and G<sub>2</sub>/M transitions, respectively offer additional targets for therapeutic intervention in suppressing deregulated cell-cycle progression in cancer.

Another protein kinase, CHK-1, plays an important role as a checkpoint in cell-cycle progression. Checkpoints are control systems that coordinate cell-cycle progression by influencing the formation, activation and subsequent inactivation of the cyclin-dependent kinases. Checkpoints prevent cell-cycle progression at inappropriate times, maintain the metabolic balance of cells while the cell is arrested, and in some instances can induce apoptosis (programmed cell death) when the requirements of the checkpoint have not been met. See, e.g., O'Connor, *Cancer Surveys*, 29, 151-182 (1997); Nurse, *Cell*, 91, 865-867 (1997); Hartwell et al., *Science*, 266, 1821-1828 (1994); Hartwell et al., *Science*, 246, 629-634 (1989).

One series of checkpoints monitors the integrity of the genome and, upon sensing DNA damage, these "DNA damage checkpoints" block cell-cycle progression in G<sub>1</sub> & G<sub>2</sub> phases, and slow progression through S phase. O'Connor, *Cancer Surveys*, 29, 151-182 (1997); Hartwell et al., *Science*, 266, 1821-1828 (1994). This action enables DNA repair processes to complete their tasks before replication of the genome and subsequent separation of this genetic material into new daughter cells takes place.

Importantly, the most commonly mutated gene in human cancer, the p53 tumor suppressor gene, produces a DNA damage checkpoint protein that blocks cell-cycle progression in G<sub>1</sub> phase and/or induces apoptosis (programmed cell death) following DNA damage. Hartwell et al., *Science*, 266, 1821-1828 (1994). The p53 tumor suppressor has also been shown to strengthen the action of a DNA damage checkpoint in G<sub>2</sub> phase of the cell-cycle. See, e.g., Bunz et al., *Science*, 28, 1497-1501 (1998);

Winters et al., *Oncogene*, 17, 673-684 (1998); Thompson, *Oncogene*, 15, 3025-3035 (1997).

Given the pivotal nature of the p53 tumor suppressor pathway in human cancer, therapeutic interventions that exploit vulnerabilities in p53-defective cancer have been actively sought. One emerging vulnerability lies in the operation of the G<sub>2</sub> checkpoint in p53 defective cancer cells. Cancer cells, because they lack G<sub>1</sub> checkpoint control, are particularly vulnerable to abrogation of the last remaining barrier protecting them from the cancer killing effects of DNA-damaging agents: the G<sub>2</sub> checkpoint. The G<sub>2</sub> checkpoint is regulated by a control system that has been conserved from yeast to humans. Important in this conserved system is a kinase, CHK-1, which transduces signals from the DNA-damage sensory complex to inhibit activation of the cyclin B/Cdc2 kinase, which promotes mitotic entry. See, e.g., Peng et al., *Science*, 277, 1501-1505 (1997); Sanchez et al., *Science*, 277, 1497-1501 (1997). Inactivation of CHK-1 has been shown to both abrogate G<sub>2</sub> arrest induced by DNA damage inflicted by either anticancer agents or endogenous DNA damage, as well as result in preferential killing of the resulting checkpoint defective cells. See, e.g., Nurse, *Cell*, 91, 865-867 (1997); Weinert, *Science*, 277, 1450-1451 (1997); Walworth et al., *Nature*, 363, 368-371 (1993); and Al-Khodairy et al., *Molec. Biol. Cell*, 5, 147-160 (1994).

Selective manipulation of checkpoint control in cancer cells could afford broad utilization in cancer chemotherapeutic and radiotherapy regimens and may, in addition, offer a common hallmark of human cancer "genomic instability" to be exploited as the selective basis for the destruction of cancer cells. A number of factors place CHK-1 as a pivotal target in DNA-damage checkpoint control. The elucidation of inhibitors of this and functionally related kinases such as Cds1/CHK-2, a kinase recently discovered to cooperate with CHK-1 in regulating S phase progression (see Zeng et al., *Nature*, 395, 507-510 (1998); Matsuoka, *Science*, 282, 1893-1897 (1998)), could provide valuable new therapeutic entities for the treatment of cancer.

Tyrosine kinases can be of the receptor type (having extracellular, transmembrane and intracellular domains) or the non-receptor type (being wholly intracellular). At least one of the non-receptor protein tyrosine kinases, namely, LCK,

is believed to mediate the transduction in T-cells of a signal from the interaction of a cell-surface protein (Cd4) with a cross-linked anti-Cd4 antibody. A more detailed discussion of non-receptor tyrosine kinases is provided in Bolen, *Oncogene*, 8, 2025-2031 (1993), which is incorporated herein by reference.

5 In addition to the protein kinases identified above, many other protein kinases have been considered to be therapeutic targets, and numerous publications disclose inhibitors of kinase activity, as reviewed in the following: McMahon et al., *Current Opinion in Drug Discovery & Development*, 1, 131-146 (1998); Strawn et al., *Exp. Opin. Invest. Drugs*, 7, 553-573 (1998); Adams et al., *Curr. Opin. Drug Disc. Dev.*, 2, 96-109 (1999), Stover et al., *Curr. Opin. Drug Disc. Dev.*, 2, 274-285 (1999), Toledo  
10 et al., *Curr. Med. Chem.*, 6, 775-805 (1999), and García-Echeverría, et al., *Med. Res. Rev.*, 20, 28-57 (2000).

There is still a need, however, for effective inhibitors of protein kinases. Moreover, as is well understood by those skilled in the art, it is desirable for kinase  
15 inhibitors to possess both high affinity for the target kinase as well as high selectivity versus other protein kinases.

#### SUMMARY OF THE INVENTION

Thus, an objective of the invention is to provide potent inhibitors of protein kinases. Another objective of the invention is to provide effective kinase inhibitors  
20 having a strong and selective affinity for a particular kinase.

These and other objectives of the invention, which will become apparent from the following description, have been achieved by the discovery of amide compounds, pharmaceutically acceptable prodrugs, pharmaceutically active metabolites, and pharmaceutically acceptable salts thereof (such compounds, prodrugs, metabolites and  
25 salts are collectively referred to as "agents") described below, which modulate and/or inhibit the activity of protein kinases.

Pharmaceutical compositions containing such agents are useful in treating various diseases and disorders associated with uncontrolled or unwanted angiogenesis and/or cellular proliferation, such as cancer, autoimmune diseases, viral diseases,  
30 fungal diseases, neurodegenerative disorders and cardiovascular diseases. Thus,

pharmaceutical compositions containing such agents are useful in the treatment of diabetic retinopathy, neovascular glaucoma, rheumatoid arthritis, and psoriasis.

Further, the agents have advantageous properties relating to modulation and/or inhibition of the kinase activity associated with VEGF-R, FGF-R, CDK

5 complexes(e.g., CDK1, CDK2, CDK4 and CDK6), CHK-1, TEK, and LCK. Thus, pharmaceutical compositions containing such agents are useful in the treatment of diseases and disorders mediated by kinase activity, such as cancer.

More particularly, the compounds are useful as anti-angiogenesis agents and as agents for modulating and/or inhibiting the activity of protein kinases, thus providing treatments for cancer or other diseases associated with cellular proliferation mediated by protein kinases.

It is understood that compounds of Formula I, II, and III may exhibit the phenomenon of tautomerism and that the formula drawings within this specification  
15   can represent only one of the possible tautomeric forms. It is to be understood that the invention encompasses any tautomeric form which modulates and/or inhibits kinase activity and is not to be limited merely to any one tautomeric form utilized within the formula drawings.

Some of the inventive compounds may exist as single stereoisomers (i.e.,  
20   essentially free of other stereoisomers), racemates, and/or mixtures of enantiomers and/or diastereomers. All such single stereoisomers, racemates and mixtures thereof are intended to be within the scope of the present invention. Preferably, the inventive compounds that are optically active are used in optically pure form.

As generally understood by those skilled in the art, an optically pure compound  
25   having one chiral center (i.e., one asymmetric carbon atom) is one that consists essentially of one of the two possible enantiomers (i.e., is enantiomerically pure), and an optically pure compound having more than one chiral center is one that is both diastereomerically pure and enantiomerically pure. Preferably, the compounds of the present invention are used in a form that is at least 90% optically pure, that is, a form  
30   that contains at least 90% of a single isomer (80% enantiomeric excess ("e.e.") or diastereomeric excess ("d.e.")), more preferably at least 95% (90% e.e. or d.e.), even

more preferably at least 97.5% (95% e.e. or d.e.), and most preferably at least 99% (98% e.e. or d.e.).

Additionally, the formulas are intended to cover solvated as well as unsolvated forms of the identified structures. For example, Formula I includes compounds of the indicated structure in both hydrated and non-hydrated forms. Other examples of solvates include the structures in combination with isopropanol, ethanol, methanol, DMSO, ethyl acetate, acetic acid, or ethanolamine.

In addition to compounds of the Formula I, II, and III, the invention includes pharmaceutically acceptable prodrugs, pharmaceutically active metabolites, and pharmaceutically acceptable salts of such compounds. Pharmaceutically active salts of such active metabolites are also included.

The term "pharmaceutically acceptable" means pharmacologically acceptable and substantially non-toxic to the subject being administered the cell-cycle control agent.

"A pharmaceutically acceptable prodrug" is a compound that may be converted under physiological conditions or by solvolysis to the specified compound or to a pharmaceutically acceptable salt of such compound.

"A pharmaceutically active metabolite" is intended to mean a pharmacologically active product produced through metabolism in the body of a specified compound or salt thereof. Metabolites of a compound may be identified using routine techniques known in the art and their activities determined using tests such as those described herein.

Prodrugs and active metabolites of a compound may be identified using routine techniques known in the art. See, e.g., Bertolini et al., J. Med. Chem., 40, 2011-2016 (1997); Shan, et al., J. Pharm. Sci., 86 (7), 765-767; Bagshawe, Drug Dev. Res., 34, 220-230 (1995); Bodor, Advances in Drug Res., 13, 224-331 (1984); Bundgaard, Design of Prodrugs (Elsevier Press 1985); and Larsen, Design and Application of Prodrugs, Drug Design and Development (Krogsgaard-Larsen et al., eds., Harwood Academic Publishers, 1991).

"A pharmaceutically acceptable salt" is intended to mean a salt that retains the biological effectiveness of the free acids and bases of the specified compound and that

is not biologically or otherwise undesirable. A compound of the invention may possess a sufficiently acidic, a sufficiently basic, or both functional groups, and accordingly react with any of a number of inorganic or organic bases, and inorganic and organic acids, to form a pharmaceutically acceptable salt. Exemplary

5 pharmaceutically acceptable salts include those salts prepared by reaction of the compounds of the present invention with a mineral or organic acid or an inorganic base, such as salts including sulfates, pyrosulfates, bisulfates, sulfites, bisulfites, phosphates, monohydrogenphosphates, dihydrogenphosphates, metaphosphates, pyrophosphates, chlorides, bromides, iodides, acetates, propionates, decanoates,  
10 caprylates, acrylates, formates, isobutyrate, caproates, heptanoates, propiolates, oxalates, malonates, succinates, suberates, sebacates, fumarates, maleates, butyne-1,4-dioates, hexyne-1,6-dioates, benzoates, chlorobenzoates, methylbenzoates, dinitrobenzoates, hydroxybenzoates, methoxybenzoates, phthalates, sulfonates, xylenesulfonates, phenylacetates, phenylpropionates, phenylbutyrates, citrates,  
15 lactates,  $\gamma$ -hydroxybutyrates, glycollates, tartrates, methane-sulfonates, propanesulfonates, naphthalene-1-sulfonates, naphthalene-2-sulfonates, and mandelates.

If the inventive compound is a base, the desired pharmaceutically acceptable salt may be prepared by any suitable method available in the art, for example,  
20 treatment of the free base with an inorganic acid, such as hydrochloric acid, hydrobromic acid, sulfuric acid, nitric acid, phosphoric acid and the like, or with an organic acid, such as acetic acid, maleic acid, succinic acid, mandelic acid, fumaric acid, malonic acid, pyrovic acid, oxalic acid, glycolic acid, salicylic acid, a pyranosidyl acid, such as glucuronic acid or galacturonic acid, an alpha-hydroxy acid, such as citric  
25 acid or tartaric acid, an amino acid, such as aspartic acid or glutamic acid, an aromatic acid, such as benzoic acid or cinnamic acid, a sulfonic acid, such as p-toluenesulfonic acid or ethanesulfonic acid, or the like.

If the inventive compound is an acid, the desired pharmaceutically acceptable salt may be prepared by any suitable method, for example, treatment of the free acid  
30 with an inorganic or organic base, such as an amine (primary, secondary or tertiary), an alkali metal hydroxide or alkaline earth metal hydroxide, or the like. Illustrative

examples of suitable salts include organic salts derived from amino acids, such as glycine and arginine, ammonia, primary, secondary, and tertiary amines, and cyclic amines, such as piperidine, morpholine and piperazine, and inorganic salts derived from sodium, calcium, potassium, magnesium, manganese, iron, copper, zinc,  
5 aluminum and lithium.

In the case of agents that are solids, it is understood by those skilled in the art that the inventive compounds and salts may exist in different crystal or polymorphic forms, all of which are intended to be within the scope of the present invention and specified formulas.

10 Therapeutically effective amounts of the agents of the invention may be used to treat diseases mediated by modulation or regulation of protein kinases. An "effective amount" is intended to mean that amount of an agent that, when administered to a mammal in need of such treatment, is sufficient to effect treatment for a disease mediated by the activity of one or more protein kinases, such as tyrosine kinases.

15 Thus, e.g., a therapeutically effective amount of a compound of the Formula I, salt, active metabolite or prodrug thereof is a quantity sufficient to modulate, regulate, or inhibit the activity of one or more protein kinases such that a disease condition which is mediated by that activity is reduced or alleviated.

The amount of a given agent that will correspond to such an amount will vary  
20 depending upon factors such as the particular compound, disease condition and its severity, the identity (e.g., weight) of the mammal in need of treatment, but can nevertheless be routinely determined by one skilled in the art. "Treating" is intended to mean at least the mitigation of a disease condition in a mammal, such as a human, that is affected, at least in part, by the activity of one or more protein kinases, such as  
25 tyrosine kinases, and includes: preventing the disease condition from occurring in a mammal, particularly when the mammal is found to be predisposed to having the disease condition but has not yet been diagnosed as having it; modulating and/or inhibiting the disease condition; and/or alleviating the disease condition.

The inventive agents may be prepared using the reaction routes and synthesis  
30 schemes as described below, employing the techniques available in the art using starting materials that are readily available.

Compounds of formula I where  $R^4$  is  $\text{CONHR}^5$  may be prepared as shown in Scheme 1.

### Scheme 1

As shown in Scheme 1, carboxylic acids of formula IV are coupled to amines of formula V to give compounds of formula I ( $R^4 = \text{CONHR}^5$ ). The coupling may be carried out employing various peptide coupling reagents, for example 1-ethyl-3-(3'-dimethylaminopropyl)carbodiimide HCl (EDC), *O*-(7-azabenzotriazol-1-yl)-*N,N,N',N'*-tetramethyluronium hexafluorophosphate (HATU), or benzotriazole-1-yl-oxy-tris-pyrrolidino-phosphonium hexafluorophosphate (pyBop), in polar aprotic solvents, such as *N,N*-dimethylformamide (DMF) or dichloromethane. Alternatively, the acid IV may be first converted to an acid chloride by treatment with, for example, oxalyl chloride or thionyl chloride, and then, without purification, reacted with amines of formula V to give compounds of formula I ( $R^4 = \text{CONHR}^5$ ).

Compounds of formula I where  $R^4$  is  $\text{NHCOR}^6$  may be prepared as shown in Scheme 2.

### Scheme 2

Carboxylic acids of formula VII are coupled to amines of formula VI to give compounds of formula I ( $R^4 = \text{NHCOR}^6$ ). The coupling may be carried out employing with various peptide coupling reagents, for example EDC, HATU, or pyBOP, in polar aprotic solvents, such as DMF or dichloromethane. Alternatively, the acid VII may be first converted to an acid chloride by treatment with, for example, oxalyl chloride or thionyl chloride, and then, without purification, reacted with amines of formula VI to give compounds of formula I ( $R^4 = \text{NHCOR}^6$ ).

Compounds of formula I-a may be prepared by the reaction shown in Scheme

3.

**Scheme 3**

- 5 Compounds of formula IX ( $R=R^4$ ) are treated with compounds of formula VIII, where Lg is a suitable leaving group such as chloride, bromide, or mesylate, in a dipolar aprotic solvent such as acetone, DMF, or DMSO, in the presence of a suitable base, such as potassium carbonate, cesium carbonate, sodium hydride, and the like, to provide, after extractive workup and conventional purification, compounds of formula
- 10 I-a. Alternatively, this reaction may be carried out in the same manner with compounds of formula XI ( $R = CO_2R^{11}$ , where  $R^{11}$  is hydrogen or a suitable carboxylic acid protecting group, such as methyl, ethyl, or benzyl) to give compounds of formula IV-a. In addition, the reaction carried out with compounds of formula IX ( $R = NH_2$ ) provides compounds of formula VI-a.

15

Compounds of formula XII, where W is a suitable group that can participate in a palladium-catalyzed coupling reaction such as bromide, iodide, or triflate, are allowed to react with acetylenes of formula XIII in the presence of a suitable palladium catalyst, such as dichlorobis(triphenylphosphine)palladium, and a copper catalyst, such as cuprous iodide, in the presence of a suitable base, such as piperidine, triethylamine or diisopropylethylamine, in an aprotic solvent, such as THF or DMF, at a temperature between 25 °C and 125 °C, for 1 to 24 hours. After extractive work-up and conventional purification, removal of the silyl protecting group is effected with, for example, either tetrabutylammonium fluoride in THF or sodium hydroxide in methanol, to provide compounds of formula XIV.

Under similar catalyzed coupling conditions as those described above, compounds of formula XV can be reacted with those of formula XIV to yield compounds of formula XVI. Catalytic hydrogenation of alkynes of formula XVI provides compounds of formula I-c after filtration and convention purification. Typical catalytic conditions include catalysts such as palladium, rhodium, preferably palladium-on-carbon, in a suitable solvent such as C<sub>1</sub>- C<sub>4</sub> alcohols, preferably ethanol.

Compounds of formula II-a may be prepared as shown in Scheme 6.

**Scheme 6**

20

Thioamides of formula XVII are treated with two molar equivalents of a suitable strong base, such as n-butyllithium or lithium diisopropylamide, in a suitable solvent, such as THF, at -78 °C to 0 °C, to give a solution of thioamide dianion, which is further

treated with less than or equal to 0.5 molar equivalents of compounds of formula XVIII. Conventional aqueous work-up and purification then provides compounds of formula XIX, which upon treatment with hydrazine, preferably in the presence of acetic acid, in ethanol at 0 °C to 50 °C, preferably at room temperature, provides

5 compounds of formula II-a.

Compounds of formula II-b may be prepared as shown in Scheme 7.

**Scheme 7**

Ketones of formula XX, where  $R^{12}$  is substituted or unsubstituted alkenyl, aryl, or heteroaryl, are converted to hydrazones of formula XXI by treatment with t-butyl carbazate and acetic acid in ethanol. Treatment of hydrazones of formula XXI with two molar equivalents of a suitable strong base, such as n-butyllithium or lithium diisopropylamide, in a suitable solvent, such as THF, at  $-78^{\circ}\text{C}$  to  $0^{\circ}\text{C}$ , generates a solution of hydrazone dianion, which is further treated with less than or equal to 0.5 molar equivalents of compounds of formula XVIII. Conventional aqueous work-up and purification then provides compounds of formula XXII, which upon further treatment with a suitable acid, such as trifluoroacetic acid, provides compounds of formula II-b.

Compounds of formula XVIII are prepared as shown in Scheme 8.

**Scheme 8**

Thus, compounds of formula XVIII-a and XVIII-b are prepared by alkylation  
 5 of compounds of formula IX with N-methoxy-N-methyl chloroacetamide in a like  
 manner to that shown in Scheme 3 above. Compounds of formula XVIII-c may be  
 prepared by (1) reaction of aldehydes of formula XXIII with the anion derived from N-  
 methoxy-N-methyl triethylphosphonoacetamide to give unsaturated amides of formula  
 XXIV, and (2) reduction of compounds of formula XXIV with, for example, hydrogen  
 10 in the presence of palladium on carbon to provide compounds of formula XVIII-c.

Other compounds of Formula I, II, and III may be prepared in manners  
 analogous to the general procedures described above or the detailed procedures  
 described in the examples herein.

The affinity of the compounds of the invention for a receptor may be enhanced  
 15 by providing multiple copies of the ligand in close proximity, preferably using a  
 scaffolding provided by a carrier moiety. It has been shown that provision of such

multiple valence compounds with optimal spacing between the moieties dramatically improves binding to a receptor. See e.g., Lee et al., *Biochem*, 23, 4255 (1984). The multivalency and spacing can be controlled by selection of a suitable carrier moiety or linker units. Such moieties include molecular supports which contain a multiplicity of functional groups that can be reacted with functional groups associated with the compounds of the invention. Of course, a variety of carriers can be used, including proteins such as BSA or HAS, a multiplicity of peptides including, for example, pentapeptides, decapeptides, pentadecapeptides, and the like. The peptides or proteins can contain the desired number of amino acid residues having free amino groups in their side chains; however, other functional groups, such as mercapto (-SH) groups or hydroxyl (-OH) groups, can also be used to obtain stable linkages.

Compounds that potentially regulate, modulate, or inhibit the protein kinase activity associated with receptors VEGF, FGF, CDK complexes, TEK, CHK-1, and LCK, among others, and which inhibit angiogenesis and/or cellular proliferation is desirable and is one preferred embodiment of the present invention. The present invention is further directed to methods of modulating or inhibiting protein kinase activity, for example in mammalian tissue, by administering an inventive agent. The activity of the inventive compounds as modulators of protein kinase activity, such as the activity of kinases, may be measured by any of the methods available to those skilled in the art, including *in vivo* and/or *in vitro* assays. Examples of suitable assays for activity measurements include those described in Parast C. et al., *BioChemistry*, 37, 16788-16801 (1998); Jeffrey et al., *Nature*, 376, 313-320 (1995); WIPO International Publication No. WO 97/34876; and WIPO International Publication No. WO 96/14843. These properties may be assessed, for example, by using one or more of the biological testing procedures set out in the examples below.

The active agents of the invention may be formulated into pharmaceutical compositions as described below. Pharmaceutical compositions of this invention comprise an effective modulating, regulating, or inhibiting amount of a compound of Formula I, II, or III and an inert, pharmaceutically acceptable carrier or diluent. In one embodiment of the pharmaceutical compositions, efficacious levels of the inventive agents are provided so as to provide therapeutic benefits involving modulation of

protein kinases. By "efficacious levels" is meant levels in which the effects of protein kinases are, at a minimum, regulated. These compositions are prepared in unit-dosage form appropriate for the mode of administration, e.g., parenteral or oral administration.

An inventive agent is administered in conventional dosage form prepared by  
5 combining a therapeutically effective amount of an agent (e.g., a compound of Formula I) as an active ingredient with appropriate pharmaceutical carriers or diluents according to conventional procedures. These procedures may involve mixing, granulating and compressing or dissolving the ingredients as appropriate to the desired preparation.

The pharmaceutical carrier employed may be either a solid or liquid.  
10 Exemplary of solid carriers are lactose, sucrose, talc, gelatin, agar, pectin, acacia, magnesium stearate, stearic acid and the like. Exemplary of liquid carriers are syrup, peanut oil, olive oil, water and the like. Similarly, the carrier or diluent may include time-delay or time-release material known in the art, such as glyceryl monostearate or glyceryl distearate alone or with a wax, ethylcellulose, hydroxypropylmethylcellulose,  
15 methylmethacrylate and the like.

A variety of pharmaceutical forms can be employed. Thus, if a solid carrier is used, the preparation can be tableted, placed in a hard gelatin capsule in powder or pellet form or in the form of a troche or lozenge. The amount of solid carrier may vary, but generally will be from about 25 mg to about 1 g. If a liquid carrier is used,  
20 the preparation will be in the form of syrup, emulsion, soft gelatin capsule, sterile injectable solution or suspension in an ampule or vial or non-aqueous liquid suspension.

To obtain a stable water-soluble dose form, a pharmaceutically acceptable salt of an inventive agent is dissolved in an aqueous solution of an organic or inorganic  
25 acid, such as 0.3M solution of succinic acid or citric acid. If a soluble salt form is not available, the agent may be dissolved in a suitable cosolvent or combinations of cosolvents. Examples of suitable cosolvents include, but are not limited to, alcohol, propylene glycol, polyethylene glycol 300, polysorbate 80, glycerin and the like in concentrations ranging from 0-60% of the total volume. In an exemplary embodiment,  
30 a compound of Formula I is dissolved in DMSO and diluted with water. The composition may also be in the form of a solution of a salt form of the active

ingredient in an appropriate aqueous vehicle such as water or isotonic saline or dextrose solution.

It will be appreciated that the actual dosages of the agents used in the compositions of this invention will vary according to the particular complex being used, the particular composition formulated, the mode of administration and the particular site, host and disease being treated. Optimal dosages for a given set of conditions can be ascertained by those skilled in the art using conventional dosage-determination tests in view of the experimental data for an agent. For oral administration, an exemplary daily dose generally employed is from about 0.001 to about 1000 mg/kg of body weight, more preferably from about 0.001 to about 50 mg/kg body weight, with courses of treatment repeated at appropriate intervals. Administration of prodrugs are typically dosed at weight levels which are chemically equivalent to the weight levels of the fully active form.

The compositions of the invention may be manufactured in manners generally known for preparing pharmaceutical compositions, e.g., using conventional techniques such as mixing, dissolving, granulating, dragee-making, levigating, emulsifying, encapsulating, entrapping or lyophilizing. Pharmaceutical compositions may be formulated in a conventional manner using one or more physiologically acceptable carriers, which may be selected from excipients and auxiliaries that facilitate processing of the active compounds into preparations which can be used pharmaceutically.

Proper formulation is dependent upon the route of administration chosen. For injection, the agents of the invention may be formulated into aqueous solutions, preferably in physiologically compatible buffers such as Hanks's solution, Ringer's solution, or physiological saline buffer. For transmucosal administration, penetrants appropriate to the barrier to be permeated are used in the formulation. Such penetrants are generally known in the art.

For oral administration, the compounds can be formulated readily by combining the active compounds with pharmaceutically acceptable carriers known in the art. Such carriers enable the compounds of the invention to be formulated as tablets, pills, dragees, capsules, liquids, gels, syrups, slurries, suspensions and the like,

for oral ingestion by a patient to be treated. Pharmaceutical preparations for oral use can be obtained using a solid excipient in admixture with the active ingredient (agent), optionally grinding the resulting mixture, and processing the mixture of granules after adding suitable auxiliaries, if desired, to obtain tablets or dragee cores. Suitable  
5 excipients include: fillers such as sugars, including lactose, sucrose, mannitol, or sorbitol; and cellulose preparations, for example, maize starch, wheat starch, rice starch, potato starch, gelatin, gum, methyl cellulose, hydroxypropylmethyl-cellulose, sodium carboxymethylcellulose, or polyvinylpyrrolidone (PVP). If desired, disintegrating agents may be added, such as crosslinked polyvinyl pyrrolidone, agar, or  
10 alginic acid or a salt thereof such as sodium alginate.

Dragee cores are provided with suitable coatings. For this purpose, concentrated sugar solutions may be used, which may optionally contain gum arabic, polyvinyl pyrrolidone, Carbopol gel, polyethylene glycol, and/or titanium dioxide, lacquer solutions, and suitable organic solvents or solvent mixtures. Dyestuffs or  
15 pigments may be added to the tablets or dragee coatings for identification or to characterize different combinations of active agents.

Pharmaceutical preparations which can be used orally include push-fit capsules made of gelatin, as well as soft, sealed capsules made of gelatin and a plasticizer, such as glycerol or sorbitol. The push-fit capsules can contain the active ingredients in  
20 admixture with fillers such as lactose, binders such as starches, and/or lubricants such as talc or magnesium stearate, and, optionally, stabilizers. In soft capsules, the active agents may be dissolved or suspended in suitable liquids, such as fatty oils, liquid paraffin, or liquid polyethylene glycols. In addition, stabilizers may be added. All formulations for oral administration should be in dosages suitable for such  
25 administration. For buccal administration, the compositions may take the form of tablets or lozenges formulated in conventional manner.

For administration intranasally or by inhalation, the compounds for use according to the present invention are conveniently delivered in the form of an aerosol spray presentation from pressurized packs or a nebuliser, with the use of a suitable  
30 propellant, e.g., dichlorodifluoromethane, trichlorofluoromethane, dichlorotetrafluoroethane, carbon dioxide or other suitable gas. In the case of a

pressurized aerosol the dosage unit may be determined by providing a valve to deliver a metered amount. Capsules and cartridges of gelatin for use in an inhaler or insufflator and the like may be formulated containing a powder mix of the compound and a suitable powder base such as lactose or starch.

5           The compounds may be formulated for parenteral administration by injection, e.g., by bolus injection or continuous infusion. Formulations for injection may be presented in unit-dosage form, e.g., in ampoules or in multi-dose containers, with an added preservative. The compositions may take such forms as suspensions, solutions or emulsions in oily or aqueous vehicles, and may contain formulatory agents such as  
10           suspending, stabilizing and/or dispersing agents.

          Pharmaceutical formulations for parenteral administration include aqueous solutions of the active compounds in water-soluble form. Additionally, suspensions of the active agents may be prepared as appropriate oily injection suspensions. Suitable lipophilic solvents or vehicles include fatty oils such as sesame oil, or synthetic fatty  
15           acid esters, such as ethyl oleate or triglycerides, or liposomes. Aqueous injection suspensions may contain substances which increase the viscosity of the suspension, such as sodium carboxymethyl cellulose, sorbitol, or dextran. Optionally, the suspension may also contain suitable stabilizers or agents which increase the solubility of the compounds to allow for the preparation of highly concentrated solutions.

20           For administration to the eye, a compound of the formula I, II, or III is delivered in a pharmaceutically acceptable ophthalmic vehicle such that the compound is maintained in contact with the ocular surface for a sufficient time period to allow the compound to penetrate the corneal and internal regions of the eye, including, for example, the anterior chamber, posterior chamber, vitreous body, aqueous humor,  
25           vitreous humor, cornea, iris/ciliary, lens, choroid/retina and sclera. The pharmaceutically acceptable ophthalmic vehicle may be an ointment, vegetable oil, or an encapsulating material. A compound of the invention may also be injected directly into the vitreous and aqueous humor.

          Alternatively, the active ingredient may be in powder form for constitution with  
30           a suitable vehicle, e.g., sterile pyrogen-free water, before use. The compounds may

also be formulated in rectal compositions such as suppositories or retention enemas, e.g, containing conventional suppository bases such as cocoa butter or other glycerides.

In addition to the formulations described above, the compounds may also be formulated as a depot preparation. Such long-acting formulations may be administered  
5 by implantation (for example, subcutaneously or intramuscularly) or by intramuscular injection. Thus, for example, the compounds may be formulated with suitable polymeric or hydrophobic materials (for example, as an emulsion in an acceptable oil) or ion-exchange resins, or as sparingly soluble derivatives, for example, as a sparingly soluble salt.

10 A pharmaceutical carrier for hydrophobic compounds is a cosolvent system comprising benzyl alcohol, a nonpolar surfactant, a water-miscible organic polymer, and an aqueous phase. The cosolvent system may be a VPD co-solvent system. VPD is a solution of 3% w/v benzyl alcohol, 8% w/v of the nonpolar surfactant polysorbate 80, and 65% w/v polyethylene glycol 300, made up to volume in absolute ethanol. The  
15 VPD co-solvent system (VPD:5W) contains VPD diluted 1:1 with a 5% dextrose in water solution. This co-solvent system dissolves hydrophobic compounds well, and itself produces low toxicity upon systemic administration. Naturally, the proportions of a co-solvent system may be varied considerably without destroying its solubility and toxicity characteristics. Furthermore, the identity of the co-solvent components may be  
20 varied: for example, other low-toxicity nonpolar surfactants may be used instead of polysorbate 80; the fraction size of polyethylene glycol may be varied; other biocompatible polymers may replace polyethylene glycol, e.g. polyvinyl pyrrolidone; and other sugars or polysaccharides may be substituted for dextrose.

Alternatively, other delivery systems for hydrophobic pharmaceutical  
25 compounds may be employed. Liposomes and emulsions are known examples of delivery vehicles or carriers for hydrophobic drugs. Certain organic solvents such as dimethylsulfoxide also may be employed, although usually at the cost of greater toxicity. Additionally, the compounds may be delivered using a sustained-release system, such as semipermeable matrices of solid hydrophobic polymers containing the  
30 therapeutic agent. Various sustained-release materials have been established and are known by those skilled in the art. Sustained-release capsules may, depending on their

chemical nature, release the compounds for a few weeks up to over 100 days.

Depending on the chemical nature and the biological stability of the therapeutic reagent, additional strategies for protein stabilization may be employed.

5 The pharmaceutical compositions also may comprise suitable solid- or gel-phase carriers or excipients. Examples of such carriers or excipients include calcium carbonate, calcium phosphate, sugars, starches, cellulose derivatives, gelatin, and polymers such as polyethylene glycols.

Some of the compounds of the invention may be provided as salts with pharmaceutically compatible counter ions. Pharmaceutically compatible salts may be  
10 formed with many acids, including hydrochloric, sulfuric, acetic, lactic, tartaric, malic, succinic, etc. Salts tend to be more soluble in aqueous or other protonic solvents than are the corresponding free-base forms.

The preparation of preferred compounds of the present invention is described in detail in the following examples, but the artisan will recognize that the chemical  
15 reactions described may be readily adapted to prepare a number of other protein kinase inhibitors of the invention. For example, the synthesis of non-exemplified compounds according to the invention may be successfully performed by modifications apparent to those skilled in the art, e.g., by appropriately protecting interfering groups, by changing to other suitable reagents known in the art, or by making routine modifications of  
20 reaction conditions. Alternatively, other reactions disclosed herein or known in the art will be recognized as having applicability for preparing other compounds of the invention.

### EXAMPLES

In the examples described below, unless otherwise indicated all temperatures  
25 are set forth in degrees Celsius and all parts and percentages are by weight. Reagents were purchased from commercial suppliers such as Aldrich Chemical Company or Lancaster Synthesis Ltd. and were used without further purification unless otherwise indicated. Tetrahydrofuran (THF) and N, N-dimethylformamide (DMF) were purchased from Aldrich in Sure seal bottles and used as received. All solvents were purified  
30 using standard methods readily known to those skilled in the art, unless otherwise indicated.

The reactions set forth below were done generally under a positive pressure of argon or nitrogen or with a drying tube, at ambient temperature (unless otherwise stated), in anhydrous solvents, and the reaction flasks were fitted with rubber septa for the introduction of substrates and reagents via syringe. Glassware was oven dried and/or heat dried. Analytical thin layer chromatography (TLC) was performed on glass-backed silica gel 60 F 254 plates and eluted with the appropriate solvent ratios (v/v), and are denoted where appropriate. The reactions were assayed by TLC and terminated as judged by the consumption of starting material.

Visualization of the TLC plates was generally done by ultraviolet visualization. Work-ups were typically done by doubling the reaction volume with the reaction solvent or extraction solvent and then washing with the indicated aqueous solutions using 25% by volume of the extraction volume unless otherwise indicated. Product solutions were dried over anhydrous  $\text{Na}_2\text{SO}_4$  prior to filtration and evaporation of the solvents under reduced pressure on a rotary evaporator and noted as solvents removed *in vacuo*. Products were purified by employing radial chromatography or flash column chromatography (Still et al., *J. Org. Chem.*, 43, 2923 (1978)), the latter using Merck grade flash silica gel (47-61  $\mu\text{m}$ ) and a silica gel: crude material ratio of about 20:1 to 100:1 unless otherwise stated. Hydrogenolysis was done at the pressure indicated in the examples or at ambient pressure.

$^1\text{H}$ -NMR spectra were recorded on an instrument operating at 300 or 500 MHz, and  $^{13}\text{C}$ -NMR spectra were recorded operating at 75 MHz. NMR spectra were obtained as  $\text{CDCl}_3$  solutions (reported in ppm), using chloroform as the reference standard (7.25 ppm and 77.00 ppm) or  $\text{CD}_3\text{OD}$  (3.4 and 4.8 ppm and 49.3 ppm), or internally tetramethylsilane (0.00 ppm) when appropriate. Other NMR solvents were used as needed. When peak multiplicities are reported, the following abbreviations are used: s (singlet), d (doublet), t (triplet), m (multiplet), q (quartet), br (broadened), dd (doublet of doublets), dt (doublet of triplets). Coupling constants, when given, are reported in Hertz (Hz).

Infrared (IR) spectra were recorded on a Perkin-Elmer FT-IR Spectrometer as neat oils, as KBr pellets, or as  $\text{CDCl}_3$  solutions, and when given are reported in wave numbers ( $\text{cm}^{-1}$ ). All melting points (mp) are uncorrected.

Unless otherwise stated, the HPLC conditions are the following: Hewlett Packard ODS Hypersil (5  $\mu$ m, 125 x 4 mm), 10% acetonitrile/0.1 M ammonium acetate from 0-2 minutes to 90% acetonitrile/0.1 M ammonium acetate at 22 minutes, 1.0 mL/minute, detection at 254 nm.

(a) A 2.6 M solution of *n*-BuLi in hexanes (7.4 mL, 19.2 mmol, 2.0 eq) was added to a solution of THF (40 mL) and ether (40 mL) and cooled to  $-78^\circ\text{C}$ . 4-Bromoisquinoline (Aldrich, 2.0 g, 9.6 mmol, 1.0 eq) was added to the anion in one portion and the dark orange solution was aged at  $-78^\circ\text{C}$  for 30 minutes to give a brown slurry. The mixture was treated with DMF (1.7 mL, 24.0 mmol, 2.5 eq) to give a

The combined organic extracts were washed with brine (200 mL), dried over magnesium sulfate, filtered and concentrated under reduced pressure to give an orange solid (1.8 g). The crude product was purified by flash chromatography over silica gel using 50% ethyl acetate/cyclohexane ( $R_f$  0.5) to give isoquinoline-4-carbaldehyde, **K-1a**, as a yellow solid (1.3 g, 84%): HPLC  $R_t$  = 8.8 min.; TLC  $R_f$  = 0.2 (5% ethyl acetate/35% cyclohexane/dichloromethane);  $^1\text{H}$  NMR (300 MHz,  $\text{CDCl}_3$ )  $\delta$  10.41 (s, 1H), 9.46 (s, 1H), 9.23 (d, 1H,  $J$  = 8.5 Hz), 8.95 (s, 1H), 8.12 (d, 1H,  $J$  = 8.1 Hz), 7.97 (t, 1H,  $J$  = 7.6 Hz), 7.78 (t, 1H,  $J$  = 7.3 Hz); MS (ESI)  $m/z$  158  $[\text{M} + \text{H}]^+$ .

(b) To a solution of 1.4 g (8.9 mmol) of isoquinoline-4-carbaldehyde, **K-1a**, in ethanol (50 mL) at 0 °C was added with sodium borohydride (372 mg, 9.8 mmol, 1.1 eq). The intermediate 1-allyl-1*H*-indol-5-ylamine, **K-7b**, was prepared as follows:

- (a) A solution of 5-nitro-1*H*-indole (Acros, 2.0 g, 13.5 mmol, 1.0 eq) in DMF (125 mL) was cooled to 0 °C, treated with sodium hydride (60% in mineral oil, 600 mg, 14.9 mmol, 1.1 eq) and stirred for 2.0 hours. After refluxing for 14 hours, most of the solvent was removed and the solution was diluted with diethyl ether. Approximately 100 mL of water was added followed by DBU (1.4 mL, 0.92 mmol) which resulted in a gummy precipitate. This heterogeneous solution was filtered through a short plug of silica gel eluting with diethyl ether. After concentration the residue was chromatographed twice with 10 to 20% ethyl acetate/hexanes resulting in 315 mg (40% yield) of N-(3,5-diallyl-4-methyl-phenyl)-2,2,2-trifluoroacetamide as a white solid.  $^1\text{H}$  NMR (300 MHz,  $\text{CDCl}_3$ )  $\delta$  7.72 (br s, 1H), 7.25 (s, 2H), 5.94 (m, 2H), 5.09 (dd,  $J = 10.2, 1.5$  Hz, 2H), 4.98 (dd,  $J = 15.4, 1.8$  Hz), 3.40 (d,  $J = 6.2$  Hz), 2.18 (s, 3H).

After heating to 80 °C for 16 h, the solution was cooled to room temperature. After concentration the residue was diluted with ethyl acetate (30 mL) and washed with water and brine and dried over sodium sulfate. Removal of the solvent led to 160 mg (95% yield) of 3,5-diallyl-4-methylaniline as an orange oil.  $^1\text{H}$  NMR (300 MHz,  $\text{CDCl}_3$ )  $\delta$  6.42 (s, 2H), 5.91 (m, 2H), 5.04 (dd,  $J = 10.6, 1.7$  Hz, 2H), 4.98 (dd,  $J = 17.2, 1.8$  Hz), 3.31 (d,  $J = 6.3$  Hz), 2.08 (s, 3H).

(a) To a solution of 156 mg (1.43 mmol) of 3-aminophenol in DMF at 0 °C was added 115 mg (2.86 mmol) of 60% sodium hydride dispersion in mineral oil. After 45 min, a slurry of 380 mg (1.57 mmol) of 5-bromo-3-chloromethylpyridine hydrochloride, **X-1a**, which was prepared from 5-bromo-3-(hydroxymethyl)pyridine (Hamel, P. et al., *J. Med. ## BIOLOGICAL TESTING: ENZYME ASSAYS

The stimulation of cell proliferation by growth factors such as VEGF, FGF, and others is dependent upon their induction of autophosphorylation of each of their respective receptor's tyrosine kinases. Therefore, the ability of a protein kinase inhibitor to block cellular proliferation induced by these growth factors is directly correlated with its ability to block receptor autophosphorylation. To measure the protein kinase inhibition activity of the compounds, the following constructs were devised.

VEGF-R2 Construct for Assay: A construct (VEGF-R2 $\Delta$ 50) of the cytosolic domain of human vascular endothelial growth factor receptor 2 (VEGF-R2) lacking the 50 central residues of the 68 residues of the kinase insert domain was expressed in a baculovirus/insect cell system. Of the 1356 residues of full-length VEGF-R2, VEGF-R2 $\Delta$ 50 contains residues 806-939 and 990-1171, and also one point mutation (E990V) within the kinase insert domain relative to wild-type VEGF-R2. See commonly assigned, co-pending U.S. Patent Application Serial No. 09/390,326, filed September 7, 1999, incorporated by reference herein, for discussion of VEGF constructs and expression systems. Autophosphorylation of the purified construct was performed by incubation of the enzyme at a concentration of 4  $\mu$ M in the presence of 3 mM ATP and 40 mM MgCl<sub>2</sub> in 100 mM Hepes, pH 7.5, containing 5% glycerol and 5 mM DTT, at 4 °C for 2 h. After autophosphorylation, this construct has been shown to possess catalytic activity essentially equivalent to the wild-type autophosphorylated kinase domain construct. See Parast et al., *Biochemistry*, 37, 16788-16801 (1998).

FGF-R1 Construct for Assay: The intracellular kinase domain of human FGF-R1 was expressed using the baculovirus vector expression system starting from the endogenous methionine residue 456 to glutamate 766, according to the residue numbering system of Mohammadi et al., *Mol. Cell. Biol.*, 16, 977-989 (1996). In addition, the construct also has the following 3 amino acid substitutions: L457V, C488A, and C584S.

LCK Construct for Assay: The LCK tyrosine kinase was expressed in insect cells as an N-terminal deletion starting from amino acid residue 223 to the end of the

protein at residue 509, with the following two amino acid substitutions at the N-terminus: P233M and C224D.

CHK-1 Construct for Assay: C-terminally His-tagged full-length human CHK-1 (FL-CHK-1) was expressed using the baculovirus/insect cell system. It contains 6 histidine residues (6 x His-tag) at the C-terminus of the 476 amino acid human CHK-1. The protein was purified by conventional chromatographic techniques.

Catalytically active truncations of CHK-1 may be exchanged for the full length CHK-1 protein. A preferred truncation comprises the kinase domain of CHK-1, which begins between amino acid residues 1 and 16 and terminates between amino acid residues 265 and 291. See commonly assigned, co-pending U.S. Patent Application Serial No. 09/460,421, filed December 14, 1999, incorporated by reference herein, for discussion of such alternate CHK-1 constructs and expression systems.

CDK2/Cyclin A Construct for Assay: CDK2 was purified using published methodology (Rosenblatt et al., *J. Mol. Biol.*, 230, 1317-1319 (1993)) from insect cells that had been infected with a baculovirus expression vector. Cyclin A was purified from *E. coli* cells expressing full-length recombinant cyclin A, and a truncated cyclin A construct was generated by limited proteolysis and purified as described previously (Jeffrey et al., *Nature*, 376, 313-320 (1995)).

CDK4/Cyclin D Construct for Assay: A complex of human CDK4 and cyclin D3, or a complex of cyclin D1 and a fusion protein of human CDK4 and glutathione-S-transferase (GST-CDK4), was purified using traditional biochemical chromatographic techniques from insect cells that had been co-infected with the corresponding baculovirus expression vectors.

TEK Construct for Assay: The intracellular kinase domain (residues 775 to 1124, with methionine added at the N-terminus) of human TEK/Tie-2 was expressed using the baculovirus vector expression system. For assay purposes, the enzyme was autophosphorylated prior to use by incubation overnight at 4 °C, at 10 µM enzyme concentration, with 4 mM ATP, 40 mM MgCl<sub>2</sub>, and 5 mM DTT in 200 mM Hepes buffer at pH 7.5, in 90:10 water:glycerol.

## VEGF-R2 Assay

### Coupled Spectrophotometric (FLVK-P) Assay

The production of ADP from ATP that accompanies phosphoryl transfer was coupled to oxidation of NADH using phosphoenolpyruvate (PEP) and a system having pyruvate kinase (PK) and lactic dehydrogenase (LDH). The oxidation of NADH was monitored by following the decrease of absorbance at 340 nm ( $\epsilon_{340} = 6.22 \text{ cm}^{-1} \text{ mM}^{-1}$ ) using a Beckman DU 650 spectrophotometer. Assay conditions for phosphorylated VEGF-R2 $\Delta$ 50 (indicated as FLVK-P in the tables below) were the following: 1 mM PEP; 250  $\mu$ M NADH; 50 units of LDH/mL; 20 units of PK/mL; 5 mM DTT; 5.1 mM poly(E<sub>4</sub>Y<sub>1</sub>); 1 mM ATP; and 25 mM MgCl<sub>2</sub> in 200 mM Hepes, pH 7.5. Assay conditions for unphosphorylated VEGF-R2 $\Delta$ 50 (indicated as FLVK in the tables) were the following: 1 mM PEP; 250  $\mu$ M NADH; 50 units of LDH/mL; 20 units of PK/mL; 5 mM DTT; 20 mM poly(E<sub>4</sub>Y<sub>1</sub>); 3 mM ATP; and 60 mM MgCl<sub>2</sub> and 2 mM MnCl<sub>2</sub> in 200 mM Hepes, pH 7.5. Assays were initiated with 5 to 40 nM of enzyme.  $K_i$  values were determined by measuring enzyme activity in the presence of varying concentrations of test compounds. The data were analyzed using Enzyme Kinetic and Kaleidagraph software.

### ELISA Assay

Formation of phosphogastrin was monitored using biotinylated gastrin peptide (1-17) as substrate. Biotinylated phosphogastrin was immobilized using streptavidin coated 96-well microtiter plates followed by detection using anti-phosphotyrosine-  
5 antibody conjugated to horseradish peroxidase. The activity of horseradish peroxidase was monitored using 2,2'-azino-di-[3-ethylbenzathiazoline sulfonate(6)] diammonium salt (ABTS). Typical assay solutions contained: 2  $\mu$ M biotinylated gastrin peptide; 5 mM DTT; 20  $\mu$ M ATP; 26 mM  $MgCl_2$ ; and 2 mM  $MnCl_2$  in 200 mM Hepes, pH 7.5. The assay was initiated with 0.8 nM of phosphorylated VEGF-R2 $\Delta$ 50. Horseradish  
10 peroxidase activity was assayed using ABTS, 10 mM. The horseradish peroxidase reaction was quenched by addition of acid ( $H_2SO_4$ ), followed by absorbance reading at 405 nm.  $K_i$  values were determined by measuring enzyme activity in the presence of varying concentrations of test compounds. The data were analyzed using Enzyme Kinetic and Kaleidagraph software.

### 15 FGF-R Assay

The spectrophotometric assay was carried out as described above for VEGF-R2, except for the following changes in concentration: FGF-R = 50 nM, ATP = 2 mM, and poly(E4Y1)=15 mM.

### LCK Assay

20 The spectrophotometric assay was carried out as described above for VEGF-R2, except for the following changes in concentration: LCK = 60 nM,  $MgCl_2$  = 40 nM, poly(E4Y1) = 20 mM.

### CHK-1 Assay

The production of ADP from ATP that accompanies phosphoryl transfer to the  
25 synthetic substrate peptide Syntide-2 (PLARTLSVAGLPGKK) was coupled to oxidation of NADH using phosphoenolpyruvate (PEP) through the actions of pyruvate kinase (PK) and lactic dehydrogenase (LDH). The oxidation of NADH was monitored by following the decrease of absorbance at 340 nm ( $\epsilon_{340}=6.22 \text{ cm}^{-1} \text{ mM}^{-1}$ ) using a HP8452 spectrophotometer. Typical reaction solutions contained: 4 mM PEP; 0.15  
30 mM NADH; 28 units of LDH/ml; 16 units of PK/ml; 3 mM DTT; 0.125 mM Syntide-2; 0.15 mM ATP; 25 mM  $MgCl_2$  in 50 mM TRIS, pH 7.5; and 400 mM NaCl. Assays

were initiated with 10 nM of FL-CHK-1.  $K_i$  values were determined by measuring initial enzyme activity in the presence of varying concentrations of test compounds. The data were analyzed using Enzyme Kinetic and Kaleidagraph software.

#### CDK2/Cyclin A and CDK4/Cyclin D Assays

5           Cyclin-dependent kinase activity was measured by quantifying the enzyme-catalyzed, time-dependent incorporation of radioactive phosphate from [ $^{32}$ P]ATP into a recombinant fragment of the retinoblastoma protein. Unless noted otherwise, assays were performed in 96-well plates in a total volume of 50  $\mu$ L, in the presence of 10 mM HEPES (N-[2-hydroxyethyl]piperazine-N'-[2-ethanesulfonic acid]) (pH 7.4), 10 mM  
10   MgCl<sub>2</sub>, 25  $\mu$ M adenosine triphosphate (ATP), 1 mg/mL ovalbumin, 5  $\mu$ g/mL leupeptin, 1 mM dithiothreitol, 10 mM  $\beta$ -glycerophosphate, 0.1 mM sodium vanadate, 1 mM sodium fluoride, 2.5 mM ethylene glycol-bis( $\beta$ -aminoethyl ether)-N,N,N'-tetraacetic acid (EGTA), 2% (v/v) dimethylsulfoxide, and 0.03 - 0.2  $\mu$ Ci [ $^{32}$ P]ATP. The substrate (0.3-0.5  $\mu$ g) was purified recombinant retinoblastoma protein fragment  
15   (Rb) (residues 386-928 of the native retinoblastoma protein; 62.3 kDa, containing the majority of the phosphorylation sites found in the native 106-kDa protein, as well as a tag of six histidine residues for ease of purification). Reactions were initiated with CDK2 (150 nM CDK2/Cyclin A complex) or CDK4 (50 nM CDK4/Cyclin D3 complex), incubated at 30°C, and terminated after 20 minutes by the addition of  
20   ethylenediaminetetraacetic acid (EDTA) to 250 mM. The phosphorylated substrate was then captured on a nitrocellulose membrane using a 96-well filtration manifold, and unincorporated radioactivity was removed by repeated washing with 0.85% phosphoric acid. Radioactivity was quantified by exposing the dried nitrocellulose membranes to a phosphorimager. Apparent  $K_i$  values were measured by assaying  
25   enzyme activity in the presence of different compound concentrations and subtracting the background radioactivity measured in the absence of enzyme. The kinetic parameters (kcat,  $K_m$  for ATP) were measured for each enzyme under the usual assay conditions by determining the dependence of initial rates on ATP concentration. The data were fit to an equation for competitive inhibition using Kaleidagraph (Synergy  
30   Software), or were fit to an equation for competitive tight-binding inhibition using the software KineTic (BioKin, Ltd.). Measured  $K_i$  values for known inhibitors against

CDK4 and CDK2 agreed with published  $IC_{50}$  values. The specific activity of CDK4 was the same whether complexed to full-length cyclin D3 or the truncated Cyclin D3 construct; both complexes also yielded very similar  $K_i$  values for selected inhibitors.

#### TEK/Tie-2 Assay

- 5           The spectrophotometric assay was carried out as described above for VEGF-R2, except for the following changes in concentration: TEK/Tie-2 = 200 nM,  $MgCl_2$  = 40 mM, and ATP = 2 mM.

#### HUVEC Proliferation Assay

- 10           This assay determines the ability of a test compound to inhibit the growth factor-stimulated proliferation of human umbilical vein endothelial cells ("HUVEC"). HUVEC cells (passage 3-4, Clonetics, Corp.) were thawed into EGM2 culture medium (Clonetics Corp) in T75 flasks. Fresh EGM2 medium was added to the flasks 24 hours later. Four or five days later, cells were exposed to another culture medium (F12K medium supplemented with 10% fetal bovine serum (FBS), 60  $\mu$ g/ml endothelial cell growth supplement (ECGS), and 0.1 mg/ml heparin). Exponentially-growing HUVEC
- 15           cells were used in experiments thereafter. Ten to twelve thousand HUVEC cells were plated in 96-well dishes in 100  $\mu$ l of rich, culture medium (described above). The cells were allowed to attach for 24 hours in this medium. The medium was then removed by aspiration and 105  $\mu$ l of starvation media (F12K+1% FBS) was added to each well.
- 20           After 24 hours, 15  $\mu$ l of test agent dissolved in 1% DMSO in starvation medium or this vehicle alone was added into each treatment well; the final DMSO concentration was 0.1%. One hour later, 30  $\mu$ l of VEGF (30 ng/ml) in starvation media was added to all wells except those containing untreated controls; the final VEGF concentration was 6 ng/ml. Cellular proliferation was quantified 72 hours later by MTT dye reduction, at
- 25           which time cells were exposed for 4 hours MTT (Promega Corp.). Dye reduction was stopped by addition of a stop solution (Promega Corp.) and absorbance at 595  $\lambda$  was determined on a 96-well spectrophotometer plate reader.

#### Cancer Cell Proliferation (MV522) Assay

- 30           The protocol for assessing cellular proliferation in cancer cells is similar to that used for assessments in HUVEC cells. Two thousand lung cancer cells (line MV522, acquired from American Tissue Cultural Collection) were seeded in growth media

(RPMI1640 medium supplemented with 2 mM glutamine and 10% FBS). Cells are allowed to attach for 1 day prior to addition of test agents and /or vehicles. Cells are treated simultaneously with the same test agents used in the HUVEC assay. Cellular proliferation is quantified by MTT dye reduction assay 72 hours after exposure to test agents. The total length of the assay is 4 days vs. 5 for HUVEC cells because MV522 cells are not exposed to starvation medium.

The results of the testing of the compounds using various assays are summarized in the table below, where a notation of “% @” indicates the percent inhibition at the stated concentration, “NT” indicates no inhibition, “slow-binding kinetics” indicates that curvature in the progress curves in the enzyme assay precluded the determination of rates, and “NT” indicates compounds “not tested” for a particular activity.

The exemplary compounds described above may be formulated into pharmaceutical compositions according to the following general examples.

Example 1: Parenteral Composition

- 5 To prepare a parenteral pharmaceutical composition suitable for administration by injection, 100 mg of a water-soluble salt of a compound of Formula I is dissolved in DMSO and then mixed with 10 mL of 0.9% sterile saline. The mixture is incorporated into a dosage unit form suitable for administration by injection.

Example 2: Oral Composition

- 10 To prepare a pharmaceutical composition for oral delivery, 100 mg of a compound of Formula I is mixed with 750 mg of lactose. The mixture is incorporated into an oral dosage unit for, such as a hard gelatin capsule, which is suitable for oral administration.

Example 3: Intraocular Composition

- 15 To prepare a sustained-release pharmaceutical for intraocular delivery, a compound of Formula I is suspended in a neutral, isotonic solution of hyaluronic acid (1.5% conc.) in phosphate buffer (pH 7.4) to form a 1% suspension.

salt of a pharmaceutically active metabolite of a compound  
according to claim 1;

30           (b) a pharmaceutically acceptable carrier, diluent, or vehicle therefor.

17. A method of treating a mammalian disease condition mediated by protein kinase activity, comprising administering to a mammal in need thereof a therapeutically effective amount of an agent selected from the group consisting of a compound according to claim 1, a  
5 pharmaceutically acceptable prodrug thereof, a pharmaceutically active metabolite thereof, and a pharmaceutically acceptable salt thereof.
18. A method according to claim 17, wherein the mammalian disease condition is associated with tumor growth, cell proliferation, or angiogenesis.
- 10 19. A method of modulating or inhibiting the activity of a protein kinase receptor, comprising contacting the kinase receptor with an effective amount of an agent selected from the group consisting of a compound according to claim 1, a pharmaceutically acceptable prodrug thereof, a pharmaceutically active metabolite thereof, and a pharmaceutically  
15 acceptable salt thereof.
20. A method according to claim 19, wherein the protein kinase receptor is a VEGF receptor.
